## WS\#2: CALORIMETRY

Measuring heat (formerly measured in calories) is called calorimetry. Now we measure heat energy in Joules (J). The equation we use is:

$$
\begin{array}{ll}
q=\mathrm{m} \times C_{\mathrm{p}} \times \Delta T & q=\text { heat energy, } \mathrm{m}=\text { mass of water, } C_{\mathrm{p}}=\text { the specific heat capacity, and } \\
\Delta T=\text { the change in temperature }\left(\text { in }{ }^{\circ} \mathrm{C} \text { or } \mathrm{K}\right)
\end{array}
$$

1. Water has a specific heat capacity of $4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$. This means it takes 4.184 J to heat 1.00 gram of water $1.00^{\circ} \mathrm{C}$.
a. How much energy will it take to heat 10.0 grams of water $1^{\circ} \mathrm{C}$ ? $\qquad$ (Ans: 41.84J)
b. How much energy is needed to heat $30.0 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ from $10.0^{\circ} \mathrm{C}$ to $50.0^{\circ} \mathrm{C}$ ? $\qquad$ (Ans: 5020.8J)
2. Let's try a standard calorimetry problem. A pot of water ( 2.5 liters of water) initially at $25.0^{\circ} \mathrm{C}$ is heated to boiling (100. ${ }^{\circ} \mathrm{C}$ ).
a. How much energy (in J ) is needed to heat the water? (The density of water is $1.00 \mathrm{~g} / \mathrm{mL}$.). (Ans: $780,000 \mathrm{~J}$ )
b. What would this amount of heat be in kJ ? $\qquad$ (Ans: 780kJ)
3. What amount of heat is released when 175 g of water cools from $100 .{ }^{\circ} \mathrm{C}$ to room temperature, $20.0^{\circ} \mathrm{C}$ ? (Ans: -59kJ)
4. We don't always have to warm up or cool down water. The specific heat capacity of copper metal is $0.39 \mathrm{~J} / \mathrm{g} .{ }^{\circ} \mathrm{C}$.
a. It is $\qquad$ (easier/more difficult) to heat up copper than to heat up water.
b. How much energy would it take to heat up a 5.20 g sample of copper from $20.0^{\circ} \mathrm{C}$ to $100 .^{\circ} \mathrm{C}$ ? (Ans: 160 J )
5. If $300 . \mathrm{J}$ of heat energy were used to heat up a 5.00 gram sample of copper metal and a 5.00 gram sample of water both starting at $10.0^{\circ} \mathrm{C}$, calculate the final temperature of each sample? (Ans: $163.8^{\circ} \mathrm{C}$ and $24.3^{\circ} \mathrm{C}$ )
Signs of $\Delta T$ and $\boldsymbol{q}:-\boldsymbol{q}$ means heat is released. $+\boldsymbol{q}$ means heat is absorbed. $\Delta T$ is always final temperature initial temperature ( $T_{\mathrm{f}}-T_{\mathrm{i}}$ ). If something is getting hotter $\left(10^{\circ} \rightarrow 30^{\circ}\right)$, the $\Delta T$ is $30-10=+20^{\circ}$. (heat is absorbed)
If something is getting cooler $\left(75^{\circ} \rightarrow 25^{\circ}\right)$, the $\Delta T$ is $25-75=-50^{\circ}$. (heat is released)
6. Suppose we mix 90.0 grams of hot water $\left(90.0^{\circ} \mathrm{C}\right)$ with 10.0 grams of cold water $\left(10.0^{\circ} \mathrm{C}\right)$. Let $x=$ the final temperature. $\mathrm{C}=4.184 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$
a. Set up an expression for the energy released (q) by the hot water $\left(\Delta q_{\text {hot }}=\mathrm{m}_{\text {hot }} \mathrm{X} C_{\mathrm{p}} \times \Delta T_{\text {hot }}\right)$
b. Set up an expression for the energy absorbed $(q)$ by the cold water $\left(\Delta q_{\text {cold }}=\mathrm{m}_{\text {cold }} \mathrm{X} C_{\mathrm{p}} \mathrm{x} \Delta T_{\text {cold }}\right)$
c. Knowing that the heat released $=-$ heat absorbed, combine the two expressions and solve for $x$. (Ans: $82^{\circ} \mathrm{C}$ )
7. We don't always have to use water. Let's use some aluminum shot. 175 grams of hot aluminum (100. ${ }^{\circ} \mathrm{C}$ ) is dropped into an insulated cup that contains 40.0 mL of ice cold water $\left(0.0^{\circ} \mathrm{C}\right)$. Follow the example above to determine the final temperature, $x$. (a) Set up an expression for the heat lost by the aluminum ( $C_{\mathrm{p}}=0.900 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$ ). (b) Set up an expression for the heat gained by the cold water. (c) Put the two expressions together (don't forget to change one of the signs) and solve for $x$. (Ans: $48.5^{\circ} \mathrm{C}$ )
8. Somewhat Confusing Definitions:

There are several terms used in this chapter that sound very similar. Use the data provided to calculate each of them to clarify the differences. I've added some "Notes" that I hope will help. 74.8 J of heat is required to raise the temperature of 18.69 g of silver from $10.0^{\circ} \mathrm{C}$ to $27.0^{\circ} \mathrm{C}$.
a. What is the heat capacity of the silver sample? $\left(\mathrm{J} /{ }^{\circ} \mathrm{C}\right)$. Note: This is a useful value only for this specific sample of silver. (Ans: $4.4 \mathrm{~J} /{ }^{\circ} \mathrm{C}$ )
b. What is the specific heat capacity of silver? $\left(\mathrm{J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$ (Ans: $\left.0.235 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$

Note: This is a useful value for any sample of silver that is heated or cooled.
This is equivalent to the $4.184 \mathrm{~J} \cdot \mathrm{~g}^{-1} \cdot{ }^{\circ} \mathrm{C}^{-1}$ that we use for water. This value is also called the specific heat.
9. $\quad 1.150 \mathrm{~g}$ of sucrose goes through combustion in a bomb calorimeter. If the temperature rose from $23.42^{\circ} \mathrm{C}$ to $27.64^{\circ} \mathrm{C}$ and the heat capacity of the calorimeter is $4.90 \mathrm{~kJ} /{ }^{\circ} \mathrm{C}$, then determine the heat of combustion of sucrose, $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$, in kJ per mole of $\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}$. (Ans: - $6160 \mathrm{~kJ} / \mathrm{mol}$ )
10. The following data was collected in an experiment similar to the Specific Heat experiment performed in class. Fill in the missing values. (Assume the calorimeter has a calorimeter constant of $0 \mathrm{~J} /{ }^{\circ} \mathrm{C}$ )
